RBFNN-based Minimum Entropy Filtering for a Class of Stochastic Nonlinear Systems

Xin Yin, Member, IEEE, Qichun Zhang, Member, IEEE, Hong Wang, Senior Member, IEEE and Zhengtao Ding, Senior Member, IEEE

Abstract—This paper presents a novel minimum entropy filter design for a class of stochastic nonlinear systems which are subjected to non-Gaussian noises. Motivated by stochastic distribution control, an output entropy model is developed using radial basis function neural network (RBFNN) while the parameters of the model can be identified by the collected data. Based upon the presented model, the filtering problem has been investigated while the system dynamics have been represented. As the model output is the entropy of the estimation error, the optimal nonlinear filter is obtained based on the Lyapunov design which makes the model output minimum. Moreover, the entropy assignment problem has been discussed as an extension of the presented approach. To verify the presented design procedure, a numerical example is given which illustrates the effectiveness of the presented algorithm. The contributions of this paper can be summarized as 1) an output entropy model is presented using neural network; 2) a nonlinear filter design algorithm is developed as the main result and 3) a solution of entropy assignment problem is obtained which is an extension of the presented framework.

Index Terms—Minimum entropy filtering, stochastic nonlinear systems, non-Gaussian distribution, radial basis function neural network

I. INTRODUCTION

SINCE Kalman filter was proposed as a linear optimal observer design [1], [2], a lot of extensions of Kalman filter have been developed, such as the extended Kalman filter (EKF) [3] and the unscented Kalman filter (UKF) [4]. However, most of these results focus on the Gaussian stochastic systems. Due to the fact that non-Gaussian noises widely exist in practice, the non-Gaussian stochastic distribution systems became a significant research topic for filtering. For example, the stochastic distribution of estimation error is investigated in [5].

Based on the B-spline approximation, the decoupled model has been presented to avoid using the partial differential equation analysis [6]. This model provides a solution to the tracking problem of the output probability density function (PDF) [7]. Moreover, trying to make the distribution as sharp as possible in practice which leads to the minimum entropy control for the non-Gaussian distribution [8]. On the other hand, the minimum entropy filtering algorithms have also been investigated [9], [10]. These results assume that the distributions of the random noises are known and the recursive formulation of probability density function leads to heavy computational load. Meanwhile, the data driven minimum entropy filter via kernel density estimation (KDE) [11] was proposed in [12]–[14]. Basically, it is very difficult to implement the filter in real-time for the stochastic nonlinear system with unknown distribution of noises since the probability density function is difficult to obtain in real-time using kernel density estimation [11]. Another approach for nonlinear non-Gaussian filtering [15] is particle filtering for which is difficult to analyze the convergence of the estimation error. Therefore, it is necessary to develop a new filtering algorithm with theoretical analysis which can be implemented in real-time for practical applications.

To achieve the objective, a nonlinear filter is designed for a class of stochastic nonlinear systems while the nonlinear dynamics of the estimation errors have been transformed to the states of the stochastic distribution model [16]. In addition, the entropy of the estimation error can be described by the extended stochastic distribution model using RBF neural network. In other words, the non-linearity can be represented by a neural network model, and then the real-time implementation can be guaranteed once the model has been trained sufficiently. Notice that any type of neural network is available to describe the output entropy which leads to the potential framework for entropy control problem.

Following this approach, in this paper, the structure of the filter is given firstly which leads to the dynamics of the estimation error. Then, the dynamics will be represented by the RBFNN-based entropy model and the filtering will be given using Lyapunov design method. In other words, the designed filtering signal can be used to minimize the entropy of estimation error while the convergence is also analyzed in mean-square sense. The simulation results are compared with the standard EKF design and the obtained better performances indicate the effectiveness of the proposed filtering algorithm.

II. FORMULATION

Consider the following discrete-time stochastic nonlinear systems,

\[ x_{k+1} = f(x_k, u_k) + w_k \]
\[ y_k = Cx_k + \bar{v}_k \] (1)
where $y$ and $u$ denote the system output and input, respectively. Suppose that the output is bounded $y \in [a, b]$, $f(\cdot)$ is a known general continuous nonlinear function, $C$ is known constant matrix, and $w$ and $v$ stand for the random noise with zero mean values.

Assumption 1: The nonlinear function $f(\cdot)$ satisfies Lipschitz condition which implies that the following inequality holds.

$$|f(x_i, u) - f(x_j, u)| \leq M |x_i - x_j|, \forall i, j \in \mathbb{Z}^+$$

(2)

where $M$ is a real positive constant.

Based on the system model, the structure of the filter can be obtained as follows:

$$\hat{x}_{k+1} = f(\hat{x}_k, u_k) + g_k$$

(3)

where $\hat{x}$ and $\hat{y}$ denote the estimated state $x$ and the estimated output $y$ while the dynamic of estimation error $\hat{x}$ is given as follows:

$$\hat{x}_{k+1} = f(x_k, u_k) - f(\hat{x}_k, u_k) - g_k + w_k$$

(4)

Similarly the output estimation error can be formulated as $\hat{y}_k = C\hat{x}_k + \hat{v}_k$. In this paper, $g_k$ will be designed by $\hat{y}$ which forms the design objective. In particular, the filter design would be completed if the entropy of the estimation error $\hat{x}$ is minimized which implies that the randomness of the estimation is minimized. Due to the fact that $\hat{x}$ is unmeasurable, the entropy of output estimation error $\hat{y}$ can be optimized equivalently to attenuate the randomness of the estimation. Therefore, Rényi entropy is considered in this paper,

$$H_{\alpha,k}(\hat{y}) = \frac{1}{1-\alpha} \log \int_a^b \gamma_k^\alpha(\hat{y}_k, g_k) d\hat{y}$$

(5)

where $\alpha \geq 0$ is the order of the entropy, $\gamma_k(\cdot)$ denotes the probability density function of the estimation error for sampling time instance $k$, which is controlled by $g_k$.

In summary, the design objective is to find nonlinear function $g_k$ to minimize the entropy $H_{\alpha,k}(\hat{y})$ for stochastic nonlinear system (1).

III. RBFNN-BASED ENTROPY MODEL

Motivated by B-spline stochastic distribution model [7], the nonlinear function $g_k$ can be obtained in a similar way to the controller design for the stochastic distribution control. Therefore, a novel RBFNN-based entropy model is presented in this section while the dynamic relationship between $H_{\alpha,k}(\hat{y})$ and $g_k$ is established. Normally, the filter design is based on the optimization of state estimation error $\hat{x}$. However the output estimation error $\hat{y}$ is also available to use if the prediction of the output entropy can be obtained. In addition, the random noise $\hat{v}_k$ is also taken into account if the relationship between $H_{\alpha,k}(\hat{y})$ and $g_k$ is described.

A. The Structure of the Model

Suppose that the probability density function of the estimation error $\hat{y}$ can be represented by a RBF neural network with weighing vector $V_k$. Thus we recall the following model[6]

$$V_{k+1} = AV_k + Bg_k$$

$$\sqrt{\gamma_k(\hat{y}_k, g_k)} = \frac{G}{\sqrt{V_k^T EV_K}} + \epsilon$$

(6)

where $V = [v_1, v_2, \ldots, v_m]^T$ is the weight vector and $G = [G_1(\hat{y}), G_2(\hat{y}), \ldots, G_m(\hat{y})]$ while $G_i(\hat{y})$ and $\epsilon$ stand for the pre-specified Gaussian basis functions for the approximation of $\gamma(\hat{y}, g)$ and the approximation residual. $E = \sum_{i=1}^m G_i(\hat{y}) G_i(\hat{y}) d\hat{y}$. Matrices $A$ and $B$ are the coefficient of the weight update equation.

Notice that the entropy (5) can be further expressed by the following formula if the order of the entropy is selected as $\alpha = 1/2$, then we have

$$H_k = 2 \log \int_a^b \sqrt{\gamma_k(\hat{y}_k, g_k)} d\hat{y}$$

(7)

Combining the model (6) and the definition of the entropy (7), the following equation can be obtained.

$$H_k = 2 \log \left( \int_a^b \frac{G}{\sqrt{V_k^T EV_k}} V_k d\hat{y} + \int_a^b \epsilon d\hat{y} \right)$$

$$= 2 \log \left( \sum_{i=1}^m \frac{v_i}{\sqrt{V_k^T EV_k}} \int_a^b G_i(\hat{y}) d\hat{y} + \int_a^b \epsilon d\hat{y} \right)$$

(8)

According to the neural network approximation theory [17], there exists a positive integer $m$ such that the error can be made to $\epsilon < \epsilon$ for any pre-specified $\epsilon > 0$. Moreover, the integral value of the pre-specified basis function $G_i(\hat{y})$ is equal to 1. As a result, Eq.(8) can be rewritten by

$$H_k = 2 \log \left( \frac{\bar{G}}{\sqrt{V_k^T EV_k}} \right)$$

(9)

where $\bar{G} = [1, 1, \ldots, 1] \in \mathbb{R}^m$.

To simplify the expression, we can further denote the weight vector as follows:

$$\bar{V}_k = \frac{V_k}{\sqrt{V_k^T EV_k}}$$

(10)

Based on this transformation, the output entropy model of the estimation error is given by

$$\bar{V}_{k+1} = \bar{A} V_k + \bar{B} g_k$$

$$H_k = 2 \log \left( \bar{G} \bar{V}_k \right)$$

(11)

where matrices $\bar{A}$ and $\bar{B}$ are the coefficient of the transformed weight update equation for $\bar{V}$. 

This article has been accepted for publication in a future issue of this journal, but has not been fully edited. Content may change prior to final publication. Citation information: DOI 10.1109/TAC.2019.2914257, IEEE Transactions on Automatic Control
B. Parametric Identification

In order to facilitate the system analysis, the elements of the coefficient matrices $A$ and $B$ should be identified. Thus we define the following function.

$$r_k = ε^T H_k$$

(12)

Transforming the presented model, the input-output format of the system can be obtained.

$$r_k = \tilde{G} V_k = \tilde{G} (I - z^{-1} A)^{-1} \tilde{B} g_{k-1}$$

(13)

with further expansion

$$r_k = \sum_{i=1}^{m} a_i r_{k-i} + \sum_{i=1}^{m} \sum_{j=1}^{m} d_{ij} g_{k-i}$$

(14)

Notice that the expression above can be further rewritten by the following format,

$$r_k = θ^T Φ_k$$

(15)

where

$$θ = [a_1, \ldots, a_m, d_{11}, \ldots, d_{1m}, \ldots, d_{m-1,1}, \ldots, d_{m-1, m}]^T$$

(16)

$$Φ_k = [r_{k-i}, \ldots, r_{k-m}, g_{k-1}, \ldots, g_{k-1}, \ldots, g_{k-m}, \ldots, g_{k-m}]^T$$

(17)

Based on Eq.(15), the unknown parametric vector $θ$ can be estimated using recursive least square (RLS) algorithm [18]:

$$θ (i + 1) = θ (i) + \frac{P (i - 1) Φ_k (\tilde{y}_k, g_k) ε (i)}{1 + Φ_k^T (\tilde{y}_k, g_k) P (i - 1) Φ_k (\tilde{y}_k, g_k)} ε (i)$$

(18)

$$P (i) = \left( I - \frac{P (i - 1) Φ_k (\tilde{y}_k, g_k)}{1 + Φ_k^T (\tilde{y}_k, g_k) P (i - 1) Φ_k (\tilde{y}_k, g_k)} \right) P (i - 1)$$

(19)

Since the RBFNN-based approximation with weights can be given for probability density function as follows, the weights $V_k$ for any sampling instance $k$ can be estimated.

$$\sqrt{\gamma_k (\tilde{y}_k, g_k)} = GV_k + e_γ$$

(21)

which leads to

$$V_k = (G^T G)^{-1} G^T \sqrt{\gamma_k (\tilde{y}_k, g_k)}$$

(22)

while the Gaussian basis functions are orthogonal then $(G^T G)^{-1}$ exists.

Moreover, the probability density function $γ_k$ and entropy $H_k$ can be approximated using the kernel density estimation based on the online/offline training with collected data set. Then the initial value of the weights can be obtained and the weights can also be adjusted for any sampling instance $k$ if it is necessary. Finally, once the parametric vector and initial weights are estimated, the matrices $A$ and $B$ can be obtained which completes the setup of the presented model.

IV. NONLINEAR FILTER DESIGN

Based upon the presented model (11), it is shown that the filtering problem has been transformed to an optimal control form. Particularly, the structure of the filter design can be described by Fig.1.

To achieve the design objective, the performance criteria can be considered which consists of the entropy and the filtering adjustment signal with weights. Without loss of generality, the following objective can be adopted to simplify the calculation,

$$J = \frac{1}{2} (R^2 + \frac{1}{2} g_k^2)$$

(24)

where $λ$ denotes a pre-specified positive real number.

To minimise this performance criterion, the first order derivative is calculated which should be equal to 0.

$$\frac{∂J}{∂g} = 0$$

(25)

which leads to

$$\frac{∂J}{∂g} = \log (GV_k) \frac{∂ \log (GV_k)}{∂g} + λg_k$$

$$= \log (GV_k) \frac{GV_k}{GV_k} + λg_k$$

$$= \frac{GV_k}{GV_k} \frac{∂V_k}{∂t} + λg_k = 0$$

(26)

Furthermore, we have

$$Q (\tilde{y}) \frac{∂V_k}{∂t} + λg_k \frac{∂g}{∂t} = 0$$

(27)

where

$$Q (\tilde{y}) = \log (GV_k) \frac{GV_k}{GV_k} ∈ R$$

(28)
Thus the nonlinear filter can be designed and the discrete-time formula can be expressed using the backward difference with the sampling time \( \Delta t \) to replace the derivative.

\[
\frac{\partial V_k}{\partial t} \approx \frac{V_k - V_{k-1}}{\Delta t}, \quad \frac{\partial g}{\partial t} \approx \frac{g_k - g_{k-1}}{\Delta t}
\]  

(29)

which leads to

\[
\lambda g_k^2 - g_k g_{k-1} + Q(\tilde{y}) (V_k - V_{k-1}) = 0
\]  

(30)

Solving this equation, the filter design can be completed by the following formula.

\[
g_k = g_{k-1} + \sqrt{\frac{g_{k-1}^2 - 4\lambda Q(\tilde{y}) (V_k - V_{k-1})}{2\lambda}} - \frac{1}{2} \frac{\partial^2 J}{\partial g^2}
\]  

(31)

where the sign in the formula can be determined by substituting \( g_k \) with the proper \( \lambda \) into following condition

\[
\frac{\partial^2 J}{\partial g^2} > 0
\]  

(32)

Moreover, the sign in Eq.(29) can be further determined by the following convergence analysis in next section.

Note that the performance criterion can also be considered as a Lyapunov function candidate. From Eq.(24), it shows that

\[
\frac{\partial J}{\partial t} = \frac{\partial J}{\partial g} \frac{\partial g}{\partial t} = 0
\]  

(33)

As we analysed that \( \frac{\partial J}{\partial t} = 0 \) using the design function \( g \), we claim that the filtering algorithm can be used to minimize the entropy of the estimation error.

As a summary, the pseudo-code of the presented filtering algorithm is given in this section.

**Algorithm 1 Nonlinear Filtering**

**Input:** \( \hat{x}_0, g_0, \hat{A}(0), \hat{B}(0), \lambda \)

**Output:** \( \hat{y}, \hat{x} \)

Measure system output \( y \) and initialization

else

- \( g_k \leftarrow g_k \)

end if

end if

end while

---

**V. Convergence Analysis**

Since the output estimation error is minimised with the presented filtering algorithm, the convergence of the estimation error \( \hat{x} \) can be further analysed in mean square sense.

The dynamics of the estimation error Eq.(4) results in

\[
E(\ddot{x}_{k+1}^2) = E\left(\dot{f}_k^2 - 2\ddot{f}_k g_k + g_k^2\right)
\]  

(34)

where \( E(\cdot) \) denotes the mean-value operation with \( \dot{f}_k = f(x_k, u_k) - f(\hat{x}_k, u_k) \).

Similarly, we have

\[
E(\dddot{x}_{k+1}^2) = E\left(\dot{f}_{k-1}^2 - 2\ddot{f}_{k-1} g_{k-1} + g_{k-1}^2\right)
\]  

(35)

which leads to

\[
E(\dddot{x}_{k+1}^2) - E(\dddot{x}_k^2) \leq E\left((\dot{f}_k - g_k)^2 + 2\dot{f}_{k-1} g_{k-1}\right)
\]  

(36)

Notice that \( 2\dot{f}_{k-1} g_{k-1} = -(\dot{f}_{k-1} - g_{k-1})^2 + \dot{f}_{k-1}^2 + g_{k-1}^2 \),

and then Eq.(36) can be further expressed by

\[
E(\dddot{x}_{k+1}^2) - E(\dddot{x}_k^2) \leq E\left((\dot{f}_k - g_k)^2 - (\dot{f}_{k-1} - g_{k-1})^2\right)
\]

+ \( \dot{f}_{k-1}^2 + g_{k-1}^2 \)

(37)

As there always exist real positive numbers \( \varepsilon_1, \varepsilon_2 \) and \( \varepsilon_3 \), the following inequalities can be satisfied.

\[
(\dot{f}_k - g_k)^2 \leq \frac{1}{\varepsilon_1}\dot{f}_k^2 + \varepsilon_2 g_k^2
\]  

(38)

\[
(\dot{f}_{k-1} - g_{k-1})^2 \geq \frac{1}{\varepsilon_1}\dot{f}_{k-1}^2 - \varepsilon_3 g_{k-1}^2
\]  

(39)

Based upon Assumption 1, there exists a positive constant \( M_k \) for each sampling instance \( k \) to satisfy inequality (2).

Furthermore, it leads to that there always exists a positive constant \( N < \max(M_k) \) such that

\[
(\dot{f}_k - g_k)^2 \leq \frac{N}{\varepsilon_1}\dddot{x}_k^2 + \varepsilon_2 g_k^2
\]  

(40)

\[
(\dot{f}_{k-1} - g_{k-1})^2 \geq \frac{N}{\varepsilon_1}\dddot{x}_{k-1}^2 - \varepsilon_3 g_{k-1}^2
\]  

(41)

Thus, Eq.(36) is transformed to

\[
E(\dddot{x}_{k+1}^2) - E(\dddot{x}_k^2) \leq \frac{N}{\varepsilon_1}(E(\dddot{x}_k^2) - E(\dddot{x}_{k-1}^2))
\]

+ \( E\left((1 + \varepsilon_3) g_{k-1}^2 + \dddot{f}_{k-1}^2 - \varepsilon_2 g_k^2\right)\)

(42)

Note that Eq.(31) can be represented as follows:

\[
g_k = g_{k-1} - \Delta k_{k-1}
\]  

(43)

where

\[
\Delta k_{k-1} = \frac{(2\lambda - 1) g_{k-1} \pm \sqrt{g_{k-1}^2 - 4\lambda Q(\tilde{y}) (V_k - V_{k-1})}}{2\lambda}
\]  

(44)
In addition, we have
\[
\varepsilon_2 g_k^2 + (1 + \varepsilon_3) g_{k-1}^2
= \varepsilon_2 (g_{k-1}^2 - 2g_{k-1}\Delta_{k-1} + \Delta_{k-1}^2) + (1 + \varepsilon_3) g_{k-1}^2
= (1 + \varepsilon_2 + \varepsilon_3) g_{k-1}^2 - \varepsilon_2 (2g_{k-1}\Delta_{k-1} - \Delta_{k-1}^2)
\] (45)
which results in the following inequality.
\[
E (\tilde{x}_{k+1}^2) - E (\tilde{x}_k^2) \leq \frac{N}{\varepsilon_1} E (\tilde{x}_k^2) + E (\tilde{x}_{k-1}^2) + (1 + \varepsilon_2 + \varepsilon_3) g_{k-1}^2 - \varepsilon_2 (2g_{k-1}\Delta_{k-1} - \Delta_{k-1}^2)
\] (46)

Since we can always find suitable positive constants \(\varepsilon_1\) and \(N\) to make the following inequality holds,
\[
0 < \frac{N}{\varepsilon_1} < 1
\] (47)
thus the estimation error is convergent if the following condition is satisfied.
\[
\tilde{x}_{k-1}^2 + (1 + \varepsilon_2 + \varepsilon_3) g_{k-1}^2 + \varepsilon_2 \Delta_{k-1}^2 - 2\varepsilon_2 g_{k-1}\Delta_{k-1} \leq 0
\] (48)

To meet Eq.(32), \(\lambda\) can be chosen as \(\lambda \geq \frac{1}{7}\), and then Eq.(44) shows that the ‘+’ sign can be used if \(g_{k-1} > 0\). Similarly, the ‘−’ sign can be used if \(g_{k-1} < 0\) such that
\[
\varepsilon_2 g_{k-1}\Delta_{k-1} > 0
\] (49)
Since \(\varepsilon_2\) can be pre-specified as a large positive constant to satisfy the inequality (40), the condition (48) is implementable.

Finally, it can be represented as
\[
|E (\tilde{x}_{k+1}^2) - E (\tilde{x}_k^2)| \leq \frac{N}{\varepsilon_1} |E (\tilde{x}_k^2) - E (\tilde{x}_{k-1}^2)|
\] (50)

It has been shown that the estimation error for each state of the presented stochastic system (1) is convergent with the filter (31), if there exist \(\varepsilon_1, \varepsilon_2, \varepsilon_3\) and \(\lambda\) meet the inequalities (47) and (48) for each time instance \(k\). In addition, the sign in Eq.(31) can be chosen following the analysis (48) and (49).

**VI. A Numerical Example**

To verify the presented filtering algorithm, the twin-level tank system is considered as a practical experiment while the structure is shown in Fig.2.

Following the system instruction in [19], the system model can be obtained as follows.
\[
x_{1,k+1} = -\frac{h}{A_1} (c_1 + k_1\sqrt{x_{1,k}} - k_0\sqrt{x_{2,k}} - x_{1,k})
+ x_{1,k} + w_{1,k}
\]
\[
x_{2,k+1} = \frac{h}{A_2} (k_2 u_{2,k} - c_2 - k_0\sqrt{x_{2,k}} - x_{1,k})
+ x_{2,k} + w_{2,k}
\]
\[
y_k = x_{1,k} + v_k
\] (51)

where \(x_1\) and \(x_2\) stand for the levels of tank 1 and tank 2. \(A_1\) and \(A_2\) are the cross-sectional area, \(c_1\) and \(c_2\) are constant parameters of the valve and pump, \(k_0, k_1\) and \(k_4\) denote the ratio of the valves, and \(h\) is the sampling time.

**Fig. 2. The structure of a twin-tank level system.**

In addition, \(w\) and \(v\) are the process noise and measurement noise, respectively.

In particular, \(A_1 = A_2 = 167.4cm^2\) while \(c_1 = 0\) and \(c_2 = 2.88\). \(k_0, k_1\) and \(k_4\) are equal to 0.7, 0.25 and 0.1, respectively. The control input \(u_2\) is set as 30 while the equilibrium points are 0.23 and 0.26 for both tanks. Moreover, \(w_k\) is subjected to Gaussian distribution with zero means and 0.1 variance, meanwhile the non-Gaussian noise \(v_k\) is given obeying the following PDF:
\[
\gamma (\omega) = \begin{cases} 5^{12} \left(\int_0^1 \omega^8 (1 - \omega)^3 d\omega\right)^{-1} \omega^8 (5 - \omega)^3, & \omega \in [0, 5] \\ 0, & \text{otherwise} \end{cases}
\] (52)

Based on the formula, we notice that the mean-value of \(\omega_k\) is nonzero. Without loss of generality, the noise \(v_k\) in the simulation is processed as \(v_k = \omega_k - E (\omega)\) in order to shift the noise mean-value.

Following the presented filtering algorithm (3) and (31), the simulation results are given in Figs 3-6. Since the system output \(y_k\) is measurable, the entropy of \(y_k\) can be estimated by KDE which implies the signal \(r_k\) in Eq.(12). Then the identification can be progressed to obtain the RBFNN model which leads to the filter design signal \(g_k\). As the investigated stochastic nonlinear system has two states, the filtering results have been shown by Fig.3 and Fig.4 separately. It shows that both \(\tilde{x}_1\) and \(\tilde{x}_2\) are very close to true values and the performances are better than standard EKF design. In addition, a further comparison for \(x_2\) is given to indicate the estimation errors in Fig.5 while the performance presented algorithm is close to particle filter design with 50 particles. Meanwhile, the performance criterion \(J\) is also given by Fig.6 while \(\lambda\) is pre-specified as 0.2. Based on the theoretical analysis and simulation results, both of the estimation errors are convergent to zero and the randomness of the filtering has been attenuated.

As a summary, the presented filtering algorithm is effective with desired performances.
Remark 1: Notice that the RBFNN model training is based on output data approximation which explains the entropy increase at initial stage in Fig.6.

VII. FURTHER DISCUSSION

This paper provides a novel design of the nonlinear filter using the RBFNN-based entropy model, and this presented model can also be applied to other research problems such as the entropy assignment and probability density function observation.

For the non-Gaussian stochastic systems, the method based on the output entropy is a significant extension comparing to the variance with the Gaussian distribution. Therefore, randomness of the systems can be described as entropy assignment problem which is similar to the co-variance assignment problem [20]. Once the nonlinear system is remodeled by the RBFNN-based entropy approximation, the entropy of the system output can be assigned as the tracking problem of the linear system. Then the performance criteria can be replaced by

\[ J = \frac{1}{8} (H_y - H_r)^2 + \frac{\lambda}{2} u^2 \]  

(53)

where \( H_r \) denotes the reference of the output entropy. Based on this criteria, the presented approach can be used to design the nonlinear control input.

Next, the output probability density function is different to estimated in real-time due to the complexity of solving the partial differential equation. In this situation, is it possible to observe the measurable output probability density function? Using the presented entropy model, the observer for output probability density function can be designed, which is similar to the observer design of the linear system.

The observer can be given as

\[ \hat{V}_{k+1} = A\hat{V}_k + Bu - L \left( e^{\frac{1}{8}H_y,k} - e^{\frac{1}{8}\hat{H}_y,k} \right) \]  

(54)

where \( L \) is the observation gain while

\[ \hat{H}_{y,k} = 2 \log \left( \hat{G}V_k \right) \]  

(55)
To design the gain $L$ to stabilize the observation error $\hat{V} = V - \hat{V}$, the closed-loop system is rewritten as

$$\hat{V}_{k+1} = (A - LG) \hat{V}_k$$

(56)

then the gain $L$ can be obtained to make the matrix $A - LG$ Hurwitz, which means

$$\lim_{k \to \infty} \sqrt{\gamma(y, u, L)} = \lim_{k \to \infty} CV_k = \sqrt{\gamma(y, u)}$$

(57)

Therefore, the weight update equation can be considered as the online updating law for the probability density function estimation which can reduce the computational complexity and guarantee the rapidity of the observation.

**VIII. CONCLUSION**

In this paper, a novel nonlinear filter design has been presented via RBFNN-based entropy model. Based on this model, the dynamic relationship between the estimation error and the nonlinear filter has been established. The filtering design is transformed to the optimal input design for the transformed entropy model, where the Lyapunov design method has been used and the minimum entropy of the estimation error has been achieved. Moreover, the convergence of the filtering has been analyzed while the practical system model based simulation results show the effectiveness of the presented filtering algorithm.
